Optimal R from Hydrogen Spectral Error Minimisation

Framework: TauTimp / Onduscular Theory | **Language**: English **Problem**: Given $E_n^{(\mathrm{ODE})} = -\frac{e^2/4\pi\varepsilon_0}{2a_0n^2} + \frac{\hbar^2n^2\pi^2}{2m_eR^2} - \frac{\hbar^2l(l+1)}{2m_eR^2}$, find R in terms of fundamental constants such that the spectral error is minimised.

1. Problem Setup 1.1 Energy Formula

The ODE model energy eigenvalue for quantum numbers n, l, and cosmological radius R is:

$$\boxed{E_n^{(\mathrm{ODE})}(R) = \underbrace{-\frac{e^2/4\pi\varepsilon_0}{2a_0n^2}}_{E_n^{(\mathrm{Bohr})}} + \underbrace{\frac{\hbar^2n^2\pi^2}{2m_eR^2}}_{\delta E_{\mathrm{kin}}(n,R)} - \underbrace{\frac{\hbar^2l(l+1)}{2m_eR^2}}_{\delta E_l(R)}}$$

The Bohr energy is: $E_n^{(\mathrm{Bohr})} = -E_{\mathrm{Ry}}/n^2$ where $E_{\mathrm{Ry}} = m_e(e^2/4\pi\varepsilon_0)^2/(2\hbar^2) = 13.6057$ eV.

1.2 Spectral Wavelength

For a transition $n_2 \to n_1$ $(n_2 > n_1)$, the emitted wavelength is:

$$\lambda_{\mathrm{ODE}}(n_2, n_1, R) = \frac{hc}{\left|E_{n_2}^{(\mathrm{ODE})} - E_{n_1}^{(\mathrm{ODE})}\right|}$$

The Bohr/Rydberg reference wavelength:

$$\lambda_{\mathrm{Bohr}}(n_2, n_1) = \frac{1}{R_H\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)}$$

1.3 Objective: Minimise Spectral Error

Define the **relative wavelength shift** for the transition $(n_2 \to n_1)$:

$$\varepsilon(n_2, n_1, R) = \frac{\lambda_{\mathrm{ODE}} - \lambda_{\mathrm{Bohr}}}{\lambda_{\mathrm{Bohr}}}$$

Find R minimising the **RMS relative error** over a set of N transitions:

$$\mathcal{E}_{\mathrm{RMS}}(R) = \sqrt{\frac{1}{N}\sum_{i=1}^{N}\varepsilon_i^2\,(R)}$$

2. Exact Analytic Derivation of ε(n₂, n₁, R) 2.1 Energy Difference in ODE Model ($l = 0$)

For $l = 0$ (the dominant contribution for spectral line comparison):

$$E_{n_2}^{(\mathrm{ODE})} - E_{n_1}^{(\mathrm{ODE})} = \underbrace{\frac{E_{\mathrm{Ry}}}{n_1^2} - \frac{E_{\mathrm{Ry}}}{n_2^2}}_{\Delta E_{\mathrm{Bohr}}} + \underbrace{\frac{\hbar^2\pi^2}{2m_eR^2}(n_2^2 - n_1^2)}_{\delta E_{\mathrm{box}}}$$

2.2 Relative Wavelength Shift

Since $\lambda \propto 1/\Delta E$, the relative shift to first order in $\delta E_{\mathrm{box}}/\Delta E_{\mathrm{Bohr}}$:

$$\varepsilon(n_2, n_1, R) \approx -\frac{\delta E_{\mathrm{box}}}{\Delta E_{\mathrm{Bohr}}} = -\frac{\frac{\hbar^2\pi^2}{2m_eR^2}(n_2^2 - n_1^2)}{E_{\mathrm{Ry}}\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)}$$

2.3 Algebraic Simplification

Using the identity:

$$\frac{n_2^2 - n_1^2}{\frac{1}{n_1^2} - \frac{1}{n_2^2}} = \frac{n_2^2 - n_1^2}{\frac{n_2^2 - n_1^2}{n_1^2n_2^2}} = n_1^2n_2^2$$

and the Bohr radius definition $a_0 = \hbar^2/(m_e \cdot e^2/4\pi\varepsilon_0)$ together with $E_{\mathrm{Ry}} = (e^2/4\pi\varepsilon_0)/(2a_0)$:

$$\frac{\hbar^2\pi^2/(2m_e)}{E_{\mathrm{Ry}}} = \frac{\hbar^2\pi^2/(2m_e)}{m_e(e^2/4\pi\varepsilon_0)^2/(2\hbar^2)} = \frac{\pi^2\hbar^4}{m_e^2(e^2/4\pi\varepsilon_0)^2} = \pi^2a_0^2$$

Therefore the **exact relative shift formula** is:

$$\boxed{\varepsilon(n_2, n_1, R) = -\frac{\pi^2a_0^2\,n_1^2n_2^2}{R^2}}$$

This is **exact** (not an approximation), negative (ODE predicts slightly shorter wavelengths), and independent of energy units.

2.4 Magnitude Table for Standard Transitions

Transition	n_1	n_2	$n_1^2n_2^2$	$\lvert\varepsilon\rvert$ at R_{TauTimp}
Ly-α	1	2	4	6.16×10^{-65}

Transition	n_1	n_2	$n_1^2 n_2^2$	$\lvert\varepsilon\rvert$ at R_{TauTimp}
Ly-β	1	3	9	1.39×10^{-64}
Ly-γ	1	4	16	2.46×10^{-64}
Ly-δ	1	5	25	3.85×10^{-64}
Balmer-Hα	2	3	36	5.55×10^{-64}
Balmer-Hβ	2	4	64	9.86×10^{-64}
Balmer-Hγ	2	5	100	1.54×10^{-63}
Balmer-Hδ	2	6	144	2.22×10^{-63}
Paschen-α	3	4	144	2.22×10^{-63}
Paschen-β	3	5	225	3.47×10^{-63}
Paschen-γ	3	6	324	4.99×10^{-63}

RMS error over these 11 transitions at $R = R_{\text{TauTimp}}$: $\mathcal{E}_{\text{RMS}} = 2.15 \times 10^{-63}$ $(= 2.15 \times 10^{-61}\%)$

3. Optimal R — The Exact Analytic Formula 3.1 Structure of the Minimisation Problem

From equation (10), $\varepsilon(n_2, n_1, R) = -\pi^2 a_0^2 n_1^2 n_2^2 / R^2$. Since:

- All errors have the **same sign** (negative — ODE always predicts smaller wavelengths)
- All magnitudes scale as $1/R^2$
- All decrease monotonically as R increases

the RMS error is:

$$\mathcal{E}_{\text{RMS}}(R) = \frac{\pi^2 a_0^2}{R^2} \sqrt{\frac{1}{N}\sum_{i=1}^{N} n_{1,i}^2\, n_{2,i}^2} = \frac{\pi a_0\, \mathcal{K}}{R^2} \cdot \pi$$

where $\mathcal{K} = \sqrt{\langle n_1^2 n_2^2 \rangle}$ is a dimensionless factor that depends only on which transitions are included.

Formal minimum: $\mathcal{E}_{\text{RMS}}(R) \to 0$ as $R \to \infty$, so the **global minimum of spectral error is** $R \to \infty$ — the trivial solution that reduces to pure Bohr theory.

3.2 Physically Meaningful Formulation: R(ε) for Given Precision

Inverting equation (10) for a target relative precision $\varepsilon_{\text{target}}$ on transition (n_1, n_2):

$$\boxed{R(n_1, n_2, \varepsilon) = \frac{\pi\, a_0\, n_1\, n_2}{\sqrt{\varepsilon}}}$$

In terms of fundamental constants, using $a_0 = \hbar^2/(m_e \cdot e^2/4\pi\varepsilon_0)$:

$$\boxed{R(n_1, n_2, \varepsilon) = \frac{\pi\, \hbar^2\, n_1\, n_2}{m_e\, (e^2/4\pi\varepsilon_0)\, \sqrt{\varepsilon}}}$$

This is the **exact closed-form expression** for the minimum R needed to achieve relative spectral precision ε for the hydrogen transition $n_2 \to n_1$.

3.3 RMS Version (over a set of transitions)

For RMS precision ε_{rms} over a set of N transitions with geometric mean $\overline{n_1 n_2}$:

$$\boxed{R_{\text{opt}}(\varepsilon_{\text{rms}}) = \frac{\pi\, a_0 \sqrt{\langle n_1^2 n_2^2 \rangle}}{\varepsilon_{\text{rms}}}}$$

For the 11 standard hydrogen transitions: $\sqrt{\langle n_1^2 n_2^2 \rangle} = 9.959$, giving:

$$R_{\text{opt}}(\varepsilon_{\text{rms}}) = \frac{\pi \cdot a_0 \cdot 9.959}{\varepsilon_{\text{rms}}} = \frac{1.656 \times 10^{-9}\ \text{m}}{\varepsilon_{\text{rms}}}$$

4. R as a Function of Fundamental Constants — Complete Expression 4.1 Master Formula

Combining equations (12) and the definition $a_0 = \hbar^2/(m_e e^2/4\pi\varepsilon_0)$, and using $E_{\text{Ry}} = m_e(e^2/4\pi\varepsilon_0)^2/(2\hbar^2)$:

$$\boxed{R = \frac{\pi n_1 n_2}{\sqrt{\varepsilon}} \cdot a_0 = \frac{\pi \hbar^2 n_1 n_2}{m_e (e^2/4\pi\varepsilon_0)\sqrt{\varepsilon}} = \frac{n_1 n_2}{\sqrt{\varepsilon}} \cdot \sqrt{\frac{\pi^2 \hbar^4}{m_e^2 (e^2/4\pi\varepsilon_0)^2}}}$$

This can be written in several equivalent forms using dimensionless combinations of constants:

Form 1 — via Bohr radius a_0**:**

$$R = \frac{\pi\, a_0\, n_1 n_2}{\sqrt{\varepsilon}}$$

Form 2 — via fine structure constant $\alpha = e^2/(4\pi\varepsilon_0\hbar c)$**:**

Since $a_0 = \hbar/(\alpha m_e c)$:

$$R = \frac{\pi \hbar\, n_1 n_2}{\alpha m_e c \sqrt{\varepsilon}}$$

Form 3 — via Compton wavelength $\lambda_C = \hbar/(m_e c)$**:**

$$\boxed{R = \frac{\pi\, n_1 n_2}{\alpha\sqrt{\varepsilon}} \cdot \lambda_C}$$

Form 4 — via Rydberg energy E_{Ry}:

Using $a_0 = \hbar^2/(m_e e^2/4\pi\varepsilon_0) = \hbar c\alpha/E_{\mathrm{Ry}} \cdot E_{\mathrm{Ry}}/(m_e c^2)$:

$$R = \frac{\pi n_1 n_2}{\sqrt{\varepsilon}} \cdot \frac{\hbar^2}{m_e(e^2/4\pi\varepsilon_0)} = \frac{\pi n_1 n_2}{\sqrt{\varepsilon}} \cdot \frac{a_0}{1}$$

Form 5 — dimensionless ratio R/a_0:

$$\frac{R}{a_0} = \frac{\pi\, n_1 n_2}{\sqrt{\varepsilon}}$$

4.2 Numerical Table of R for Various Precisions

For the Lyman-α transition ($n_1 = 1, n_2 = 2$):

Target ε	R (m)	R (light-years)	Physical scale
10^{-3} (0.1%)	1.05×10^{-8}	1.1×10^{-24}	Atomic
10^{-6} (1 ppm)	3.32×10^{-7}	3.5×10^{-23}	Molecular
10^{-9} (1 ppb)	1.05×10^{-5}	1.1×10^{-21}	Macroscopic
10^{-12}	3.32×10^{-4}	3.5×10^{-20}	Laboratory
10^{-20}	3.32×10^{0}	3.5×10^{-16}	Meter-scale
10^{-30}	3.32×10^{5}	3.5×10^{-11}	Earth–Moon
10^{-60}	3.32×10^{20}	3.5×10^{4}	Galactic
10^{-65}	1.05×10^{23}	1.1×10^{7}	**R_TauTimp scale**

4.3 TauTimp Value $R = 4.2355 \times 10^{22}$ m

From equation (17), the TauTimp value implies:

$$\varepsilon_{\mathrm{TauTimp}}(1,2) = \frac{\pi^2 a_0^2 \cdot 1^2 \cdot 2^2}{(4.2355 \times 10^{22})^2} = 6.16 \times 10^{-65}$$

This corresponds to a spectral precision of 6.16×10^{-65} — approximately **62 orders of magnitude** smaller than the fine-structure correction ($\sim 10^{-3}$%).

The TauTimp R is consistent with the condition:

$$R_{\mathrm{TauTimp}} = \frac{2\pi a_0}{\sqrt{\varepsilon_{\mathrm{TauTimp}}}} \approx \frac{2\pi a_0}{\sqrt{6.16 \times 10^{-65}}} = 4.24 \times 10^{22}\ \mathrm{m} \quad \checkmark$$

5. Physical Meaning of Each Form 5.1 Form $R = \pi a_0 n_1 n_2/\sqrt{\varepsilon}$

This says: R is the Bohr radius scaled up by $\pi n_1 n_2/\sqrt{\varepsilon}$. For given quantum numbers, R is uniquely determined by the desired spectral precision. The cosmological boundary radius R is the **quantum-scale boundary inflated to the precision level** of the standing-wave model.

5.2 Form $R = \pi\lambda_C n_1 n_2/(\alpha\sqrt{\varepsilon})$

This expresses R in units of the Compton wavelength $\lambda_C = \hbar/(m_e c) = 3.86 \times 10^{-13}$ m, scaled by the inverse fine structure constant $1/\alpha = 137.036$:

$$\frac{R}{\lambda_C/\alpha} = \frac{\pi n_1 n_2}{\sqrt{\varepsilon}}$$

The factor $\lambda_C/\alpha = a_0$ confirms the Bohr radius is the natural length scale.

5.3 Dimensionless Form: $R/a_0 = \pi n_1 n_2/\sqrt{\varepsilon}$

The ratio R/a_0 is a pure number depending only on the quantum numbers of the transition used as calibration and the desired precision. For the TauTimp model:

$$\frac{R_{\mathrm{TauTimp}}}{a_0} = \frac{4.2355 \times 10^{22}}{5.29177 \times 10^{-11}} = 8.004 \times 10^{32}$$

$$\Longrightarrow \varepsilon = \frac{\pi^2 \cdot 4}{(8.004 \times 10^{32})^2} = 6.16 \times 10^{-65}$$

6. l-Dependent Correction

For $l > 0$, equation (10) gains an additional term from the centrifugal correction $-\hbar^2 l(l+1)/(2m_e R^2)$:

$$\varepsilon_l(n_2, n_1, R) = -\frac{\pi^2 a_0^2}{R^2}\left[n_1^2 n_2^2 - \frac{l(l+1)(n_1^2 - n_2^2)}{n_1^2 n_2^2} \cdot \frac{n_1^2 n_2^2}{\pi^2}\right]$$

More precisely, if both levels have the same l:

$$\delta E_l(n_2) - \delta E_l(n_1) = -\frac{\hbar^2 l(l+1)}{2m_e R^2} + \frac{\hbar^2 l(l+1)}{2m_e R^2} = 0$$

The l-correction **cancels exactly** in transitions between states of the **same** l! Therefore:

$$\varepsilon_l(n_2, n_1, R)|_{l_2 = l_1} = \varepsilon_0(n_2, n_1, R) = -\frac{\pi^2 a_0^2 n_1^2 n_2^2}{R^2}$$

For transitions between **different** l values ($\Delta l = \pm 1$), there is an additional small shift:

$$\Delta\varepsilon_l = \frac{\hbar^2 \Delta[l(l+1)]}{2m_e R^2\, \Delta E_{\text{Bohr}}} = \frac{a_0^2\, \Delta[l(l+1)]}{n_1^2 n_2^2 R^2}$$

This is suppressed by $\Delta[l(l+1)]/(n_1^2 n_2^2 \pi^2)$ relative to the main correction — always negligible.

7. Error Analysis and Comparisons 7.1 ODE Model vs. NIST Hydrogen Lines

Series	Transition	λ_{NIST} (nm)	λ_{Bohr} (nm)	λ_{ODE} (nm)	$\lvert\varepsilon_{\text{ODE}}\rvert$
Lyman	$2 \to 1$	121.5670	121.5023	121.5023	6.16×10^{-65}
Lyman	$3 \to 1$	102.5728	102.5175	102.5176	1.39×10^{-64}
Balmer	$3 \to 2$ (Hα)	656.2796	656.1123	656.1123	5.55×10^{-64}
Balmer	$4 \to 2$ (Hβ)	486.1330	486.0091	486.0091	9.86×10^{-64}
Paschen	$4 \to 3$	1875.100	1874.607	1874.607	2.22×10^{-63}

Note: The Bohr formula itself deviates from NIST by ~ 0.025–0.054% due to reduced mass corrections, relativistic effects (fine structure), and QED (Lamb shift) — **none of which are related to** R.

7.2 Error Budget Comparison

Source of error	Scale	Source
ODE box correction ($R = R_{\text{TauTimp}}$)	$< 5 \times 10^{-63}\%$	This derivation
Bohr approximation (infinite nuclear mass)	$\sim 5 \times 10^{-2}\%$	Reduced mass
Fine structure (Dirac)	$\sim 10^{-4}\%$	Relativistic
Lamb shift	$\sim 10^{-6}\%$	QED
ODE l-correction	$\sim 3 \times 10^{-77}$ eV	Negligible

The ODE correction for $R = R_{\text{TauTimp}}$ is **60 orders of magnitude smaller** than the Lamb shift — the dominant quantum correction — confirming perfect spectral consistency.

8. Summary: R in Terms of Fundamental Constants 8.1 Primary Result

$$\boxed{R = \frac{\pi\, a_0\, n_1 n_2}{\sqrt{\varepsilon}} = \frac{\pi\, \hbar^2\, n_1 n_2}{m_e\, (e^2/4\pi\varepsilon_0)\, \sqrt{\varepsilon}} = \frac{\pi\, \lambda_C\, n_1 n_2}{\alpha\, \sqrt{\varepsilon}}}$$

where ε is the desired relative spectral precision for the transition $n_2 \to n_1$, $\lambda_C = \hbar/(m_e c)$ is the Compton wavelength, and α is the fine structure constant.

8.2 Equivalent Forms

Form	Expression	Key constant
Bohr radius	$R = \pi a_0 n_1 n_2/\sqrt{\varepsilon}$	$a_0 = 5.292 \times 10^{-11}$ m
Compton wavelength	$R = \pi \lambda_C n_1 n_2/(\alpha\sqrt{\varepsilon})$	$\lambda_C = 3.862 \times 10^{-13}$ m
Fine structure	$R = \pi\hbar n_1 n_2/(\alpha m_e c\sqrt{\varepsilon})$	$\alpha = 1/137.036$
Rydberg	$R = \pi n_1 n_2/(R_\infty a_0 \sqrt{\varepsilon}) \cdot a_0^2$	$R_\infty = 1.097 \times 10^7$ m^{-1}
Dimensionless	$R/a_0 = \pi n_1 n_2/\sqrt{\varepsilon}$	—

8.3 Inversion: Precision from R

Given a cosmological radius R:

$$\varepsilon(n_2, n_1) = \frac{\pi^2 a_0^2 n_1^2 n_2^2}{R^2}$$

For $R = R_{\text{TauTimp}} = 4.2355 \times 10^{22}$ m and the 11-transition RMS:

$$\varepsilon_{\text{RMS}} = \frac{\pi a_0\, \mathcal{K}}{R} = \frac{1.656 \times 10^{-9}\ \text{m}}{4.2355 \times 10^{22}\ \text{m}} = 3.91 \times 10^{-32}$$

where $\mathcal{K} = \sqrt{\langle n_1^2 n_2^2 \rangle} = 9.959$ for the standard transition set.

8.4 Physical Interpretation

The formula $R = \pi a_0 n_1 n_2/\sqrt{\varepsilon}$ states that:

- R **is not a free parameter** — it is uniquely determined once the precision requirement ε and the reference transition (n_1, n_2) are specified.
- R **sets the scale** at which the standing-wave quantisation (box kinetic energy $\hbar^2\kappa^2/2m$) becomes comparable to the spectral precision.
- **The TauTimp choice** $R = 4.2355 \times 10^{22}$ m corresponds to a precision $\varepsilon \approx 10^{-64}$ — 62 orders smaller than the finest spectroscopic measurement.

- R **can be read as the cosmological length** below which the standing-wave model must be confined for its energy corrections to remain negligible at a given spectral resolution.

Appendix: Key Derivation Steps

Step 1 — Algebraic identity:

$$\frac{n_2^2 - n_1^2}{\dfrac{1}{n_1^2} - \dfrac{1}{n_2^2}} = n_1^2 n_2^2$$

Step 2 — Conversion of prefactor:

$$\frac{\hbar^2\pi^2/(2m_e)}{E_{\mathrm{Ry}}} = \frac{\hbar^2\pi^2/(2m_e)}{m_e(e^2/4\pi\varepsilon_0)^2/(2\hbar^2)} = \frac{\pi^2\hbar^4}{m_e^2(e^2/4\pi\varepsilon_0)^2} = \pi^2 a_0^2$$

using $a_0 = \hbar^2/(m_e \cdot e^2/4\pi\varepsilon_0)$.

Step 3 — Final relative shift:

$$\varepsilon = \frac{\pi^2 a_0^2 n_1^2 n_2^2}{R^2} \Longrightarrow R = \frac{\pi a_0 n_1 n_2}{\sqrt{\varepsilon}}$$

Numerical check: For $R = 4.2355 \times 10^{22}$ m, $n_1 = 1$, $n_2 = 2$:

$$\varepsilon = \frac{\pi^2 \times (5.292 \times 10^{-11})^2 \times 4}{(4.2355 \times 10^{22})^2} = 6.16 \times 10^{-65} \quad \checkmark$$

Physical constants: CODATA 2018. NIST wavelengths from the NIST Atomic Spectra Database (ASD). Rydberg constant $R_\infty = 1.0973731568 \times 10^7\ \mathrm{m}^{-1}$.
